**Experiment: 1**

**AIM:** Interfacing LED bank to 8051 microcontroller using timer with interrupt.

**PREREQUISITE:**

Before starting this lab, students should be familiar with:

- Basics of 8051 microcontroller architecture and pin configuration.
- LED interfacing techniques with microcontrollers.
- Timer and interrupt concepts in embedded systems.
- Keil  $\mu$ Vision and Nuvoton ISP-ICP Utility tools

**OBJECTIVE:**

- By the end of this experiment, students will be able to:
- Understand the working of 8051 timers and interrupts.
- Configure timer interrupts for generating periodic signals.
- Interface LED bank to 8051 and control it using timer interrupts.
- Develop and simulate programs in Keil software.

**HARDWARE REQUIREMENTS:**

- 8051 microcontroller Development Board (Arise51 V1.1)
- USB Cable (To program and power the board)
- Power Adapter (optional)
- FRC Cables for connecting peripherals
- Pin to Pin Connectors for connecting peripherals
- Personal Computer (PC) or Laptop

**SOFTWARE REQUIREMENTS:**

- Keil  $\mu$ Vision Software
- Nuvoton ISP-ICP Utility Application
- CP2102 Drivers for USB to Serial Converter

## DEPARTMENT OF ELECTRONICS AND COMPUTER ENGINEERING

### **THEORY:**

#### **1) Introduction:**

An LED bank is a set of multiple LEDs connected to the output port of a microcontroller. By programming the microcontroller, LEDs can be turned ON or OFF in specific patterns or sequences.

The 8051 microcontroller includes two timers (Timer 0 and Timer 1) that can be used to generate accurate time delays or periodic interrupts. Interrupts are signals that temporarily stop the main program to execute a specific subroutine (ISR - Interrupt Service Routine), and then return to the main program.

#### **2) Timer Operation in 8051:**

Timers in 8051 can operate in different modes (Mode 0, 1, 2, and 3). In Mode 1, the timer works as a 16-bit timer. The timer counts from 0000H to FFFFH, and when it overflows, it sets the TF flag, which can trigger an interrupt if enabled.

#### **3) Interrupt System:**

8051 has five interrupt sources:

- External Interrupt 0 (INT0)
- Timer 0 Overflow Interrupt
- External Interrupt 1 (INT1)
- Timer 1 Overflow Interrupt
- Serial Communication Interrupt

When an interrupt occurs, the processor executes the corresponding ISR.

#### **4) LED Interfacing:**

LEDs are connected to one of the ports (commonly P1 or P2) of 8051 via current-limiting resistors. A logic HIGH or LOW signal turns each LED ON or OFF depending on the configuration.

#### **5) Working Principle:**

In this experiment, Timer 0 is configured in Mode 1 to generate interrupts at regular intervals. Each time an interrupt occurs, the ISR toggles the output pattern on the LED bank, resulting in blinking or shifting patterns.

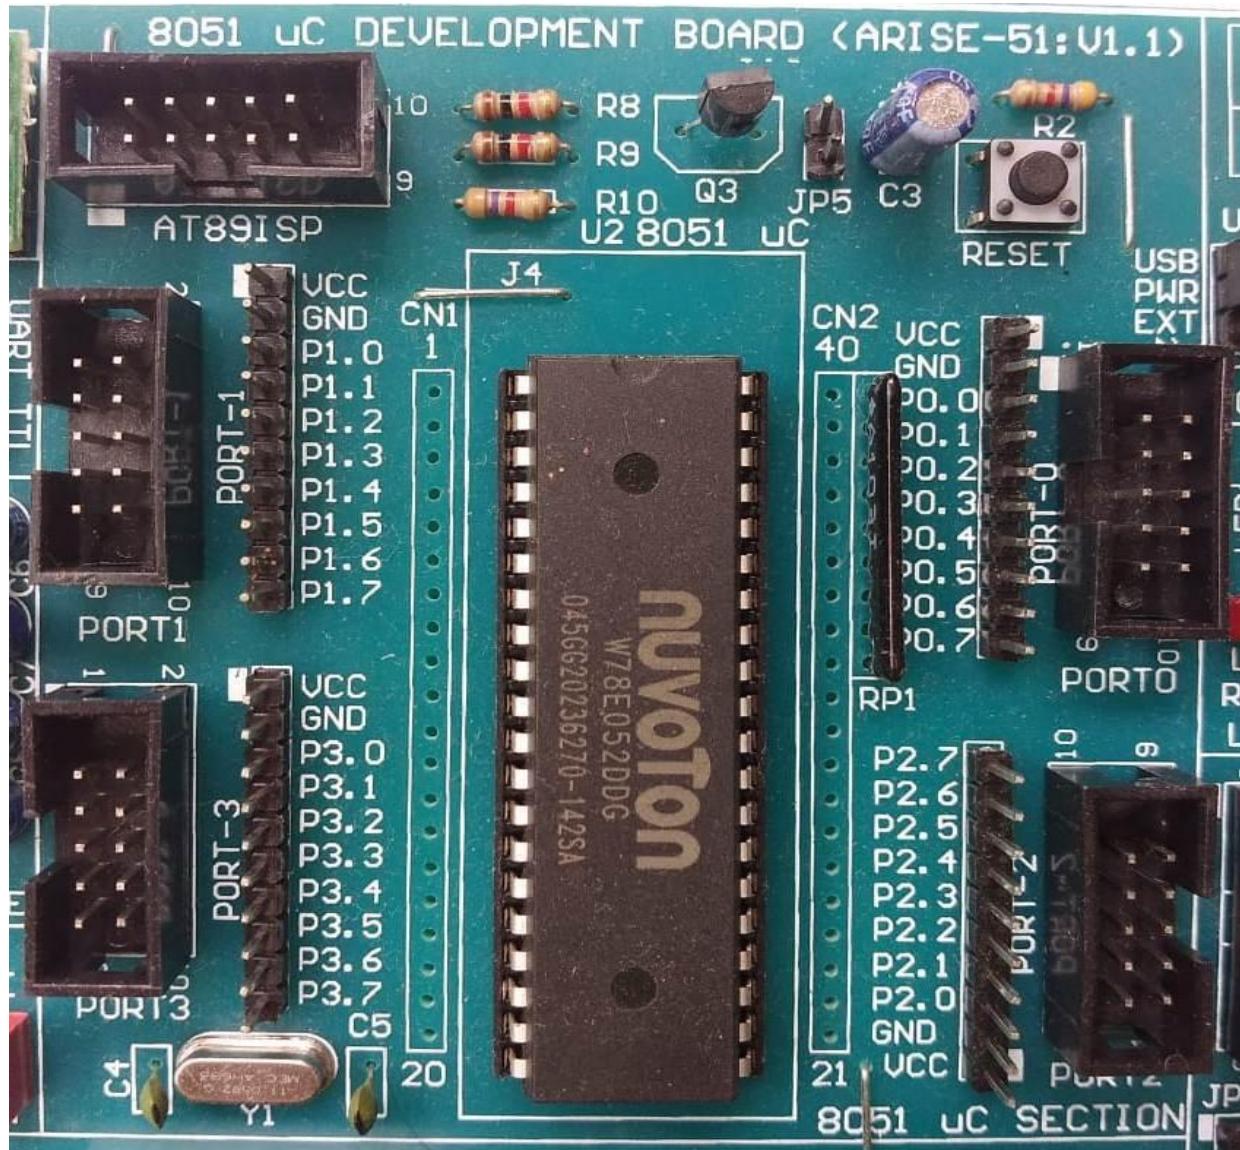

## **DEPARTMENT OF ELECTRONICS AND COMPUTER ENGINEERING**

## 6)On-board peripherals and Connection Details

## 1. Microcontroller Section

This section consists on minimum circuit of 8051 microcontroller i.e clock circuit, reset circuit, ISP Connector and Port Pins. All Ports pin available on 10 FRC and Berg strip connector as shown in figure below. FRC Connector AT89ISP is used for programming the AT89 series microcontroller from Atmel. Serial Port ISP supported by 8051 microcontrollers from NXP and Nuvoton. Therefore we are using USB to Serial converter for downloading the Hex File into microcontroller.

Reset button is used to reset the microcontroller. Clock circuit consists of 11.0592MHz crystal. Therefore while calculation of baud rate, timer delay the FSOC is taken as 11.0592MHz only.

## DEPARTMENT OF ELECTRONICS AND COMPUTER ENGINEERING

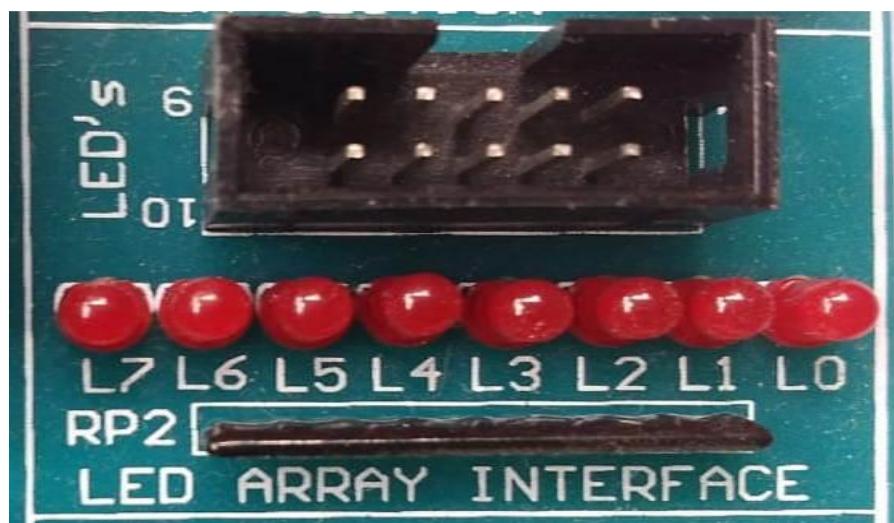

### 2. Power Section

The board can be powered using 9-12V DC adapter or from USB using proper jumper setting. The JP1 connector is used to select the proper power source. Make sure short link in correct position.

### 3. LED Section

This section consists of 8 LED's for digital output. LED's are connected in Common Cathode Mode. The LED's can be interfaced to any pin/ pins of microcontroller using pin to pin connector or 10-FRC Connector.

### Experiment: 2

**AIM:** Interfacing Seven Segment Display to 8051 microcontroller.

#### PREREQUISITE:

Before starting this lab, students should be familiar with:

- Basics of 8051 microcontroller architecture and pin configuration.
- Concept of seven segment display (Common Anode / Common Cathode).
- Working of GPIO (Input/Output) pins in 8051.
- Keil  $\mu$ Vision and Nuvoton ISP-ICP Utility tools

#### OBJECTIVE:

By the end of this experiment, students will be able to:

- Understand the working of seven segment display.
- Interface a seven segment display to 8051 microcontroller.
- Display digits (0–9) on the display through programming.
- Simulate and implement the interfacing program using Keil software.

#### HARDWARE REQUIREMENTS:

- 8051 microcontroller Development Board (Arise51 V1.1)
- USB Cable (To program and power the board)
- Power Adapter (optional)
- FRC Cables for connecting peripherals
- Pin to Pin Connectors for connecting peripherals
- Personal Computer (PC) or Laptop

#### SOFTWARE REQUIREMENTS:

## DEPARTMENT OF ELECTRONICS AND COMPUTER ENGINEERING

### **THEORY:**

#### **1) Introduction:**

A Seven Segment Display (SSD) is an electronic display device used to display decimal numbers (0–9) and some alphabets. It consists of seven LEDs arranged in a specific pattern to form digits. Each LED is labeled as ‘a’ to ‘g’, and by turning ON/OFF specific segments, different numbers can be displayed.

#### **2) Types of Seven Segment Displays:**

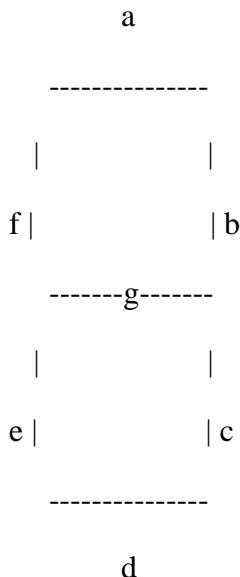

- Common Cathode (CC): All cathode terminals of LEDs are connected together to ground.
- Common Anode (CA): All anode terminals of LEDs are connected together to VCC.

In this experiment, a \*\*Common Anode\*\* seven segment display is used.

#### **3) Segment Configuration:**

Each segment (a–g) is connected to one port pin of the 8051 microcontroller. To display a digit, the corresponding binary code is sent to the port.

#### **Basic Concept: 7-Segment Layout**

Each digit (0–9) is formed by turning ON/OFF certain LEDs labelled **a–g** (plus an optional dot ‘dp’).

Each segment corresponds to one bit in an **8-bit pattern** (7 for segments + 1 for the dot).

# Zeal Education Society's ZEAL COLLEGE OF ENGINEERING & RESEARCH, PUNE – 41

## DEPARTMENT OF ELECTRONICS AND COMPUTER ENGINEERING

### Bit Position Assignment

For a **common anode 7-segment**, each segment lights up when its pin is driven **LOW (0)**.

Typical bit assignment (MSB → LSB):

Bit	Segment	Function
D7	a	Top segment
D6	b	Upper right
D5	c	Lower right
D4	d	Bottom
D3	e	Lower left
D2	f	Upper left
D1	g	Middle
D0	dp	Decimal point (optional)

### How each code is derived (quick recipe)

1. Choose which segments (a–g, dp) must be ON for the digit.
2. For each segment that is ON, set its corresponding bit to **0** (because common anode).
3. For segments that are OFF, set the bit to **1**.
4. Write the 8-bit pattern (D7→D0) and convert to hex.

**Example — digit 2:** segments a, b, d, e, g are ON.

- a=0, b=0, c=1, d=0, e=0, f=1, g=0, dp=1 → 10100100 → 0xA4.

### 4) Interfacing with 8051:

The seven segment display is interfaced to Port 2 of the 8051 microcontroller. Each pin of the port controls one segment of the display. By sending appropriate hex codes to the port, the required digit is displayed.

### 5) Working Principle:

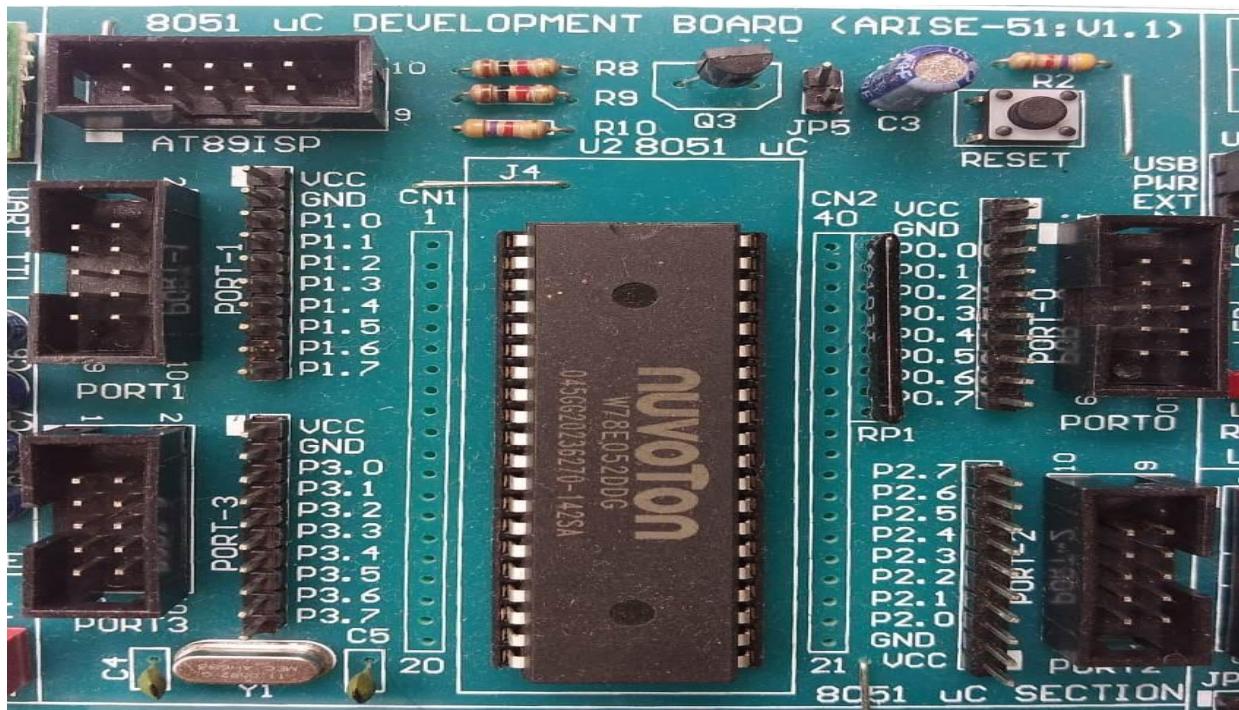

In this experiment, the microcontroller sequentially displays digits from 0 to 9 with a delay between each number. This is achieved by repeatedly writing segment codes to the output port.

### 6) On-board peripherals and Connection Details

#### 1. Microcontroller Section

## DEPARTMENT OF ELECTRONICS AND COMPUTER ENGINEERING

### SOFTWARE REQUIREMENTS:

- Keil µVision Software
- Nuvoton ISP-ICP Utility Application
- CP2102 Drivers for USB to Serial Converter

### THEORY:

#### 1) Introduction:

A 16x2 Liquid Crystal Display (LCD) is one of the most commonly used display devices in embedded systems. It can display 16 characters per line on two lines. LCD modules are widely used because they are easy to program, inexpensive, and consume low power.

#### 2) LCD Pin Configuration:

The standard 16x2 LCD has 16 pins:

1. VSS – Ground
2. VCC – +5V Supply
3. VEE – Contrast Adjustment (connected to potentiometer)
4. RS – Register Select (0: Command, 1: Data)
5. RW – Read/Write (0: Write, 1: Read)
6. EN – Enable Signal (High-to-Low pulse)
- 7–14. D0–D7 – Data Lines
15. LED+ – Backlight Anode
16. LED– – Backlight Cathode

#### 3) Interfacing LCD with 8051:

The LCD is connected to Port 2 for data (D0–D7) and Port 3 pins (P3.0, P3.1, P3.2) for control signals (RS, RW, EN). Commands and data are sent by setting RS, RW, and pulsing EN to latch the data.

#### 4) Common LCD Commands:

- 0x38 – Initialize LCD in 8-bit, 2-line, 5x7 format
- 0x0C – Display ON, Cursor OFF
- 0x01 – Clear Display
- 0x06 – Increment Cursor
- 0x80 – Move cursor to first line
- 0xC0 – Move cursor to second line

#### 5) Working Principle:

When the microcontroller sends a command, the RS pin is kept low. When it sends data, the RS pin is high. RW is low for writing. After each command or data, the EN pin is toggled to latch the value.

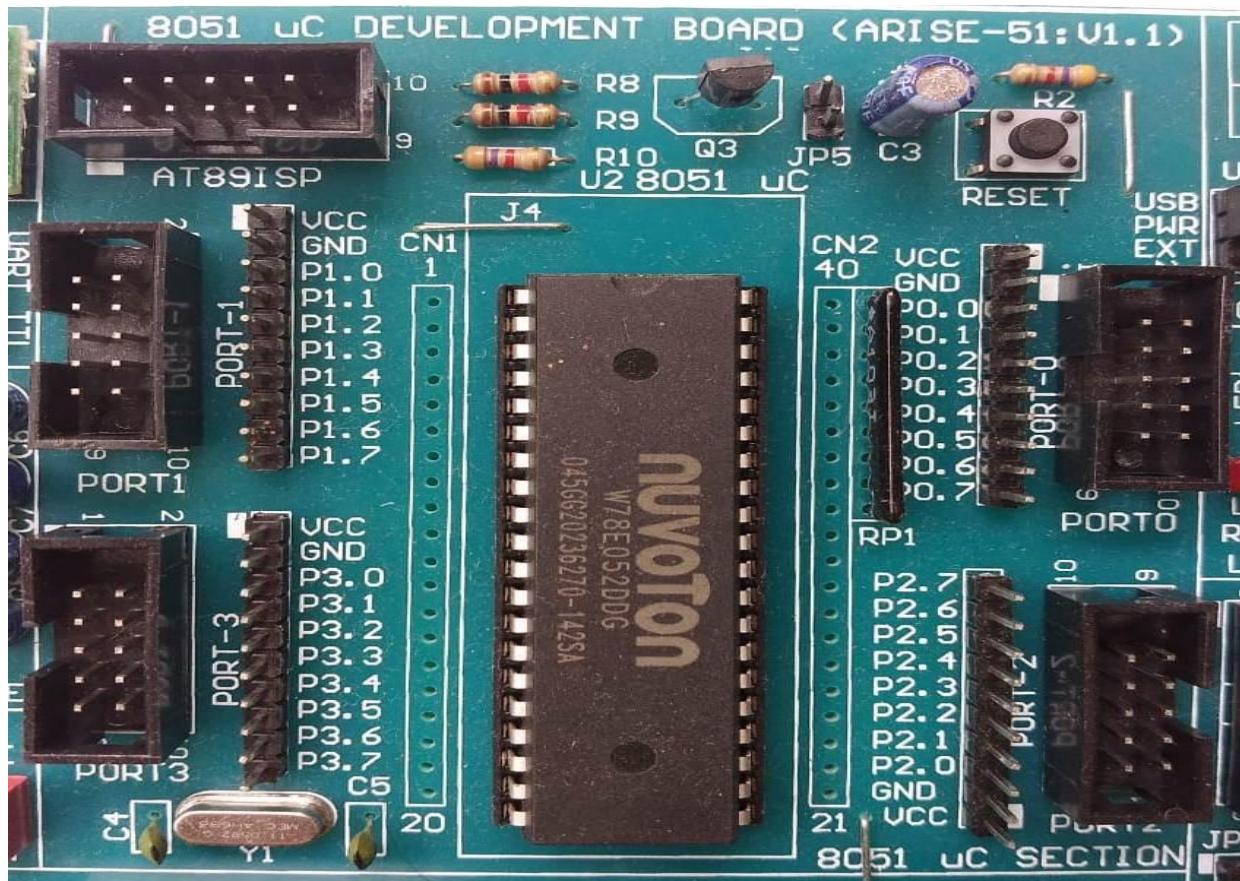

## DEPARTMENT OF ELECTRONICS AND COMPUTER ENGINEERING

### SOFTWARE REQUIREMENTS:

- Keil µVision Software
- Nuvoton ISP-ICP Utility Application
- CP2102 Drivers for USB to Serial Converter

### THEORY:

#### 1) Introduction:

A stepper motor is an electromechanical device that converts electrical pulses into discrete mechanical steps. The rotation angle of the motor is proportional to the number of input pulses. Stepper motors are used in precise motion control applications such as robotics, printers, and CNC machines.

#### 2) Working Principle:

A stepper motor operates on the principle of electromagnetism. When the stator coils are energized in a specific sequence, the rotor aligns itself with the magnetic field, producing rotation in steps. By changing the sequence of excitation, the motor can rotate clockwise or counterclockwise.

#### 3) Types of Stepper Motors:

- Unipolar Stepper Motor – Each winding has a center tap. It is easier to drive using ULN2003.
- Bipolar Stepper Motor – Requires full H-bridge drivers such as L293D.

#### 4) Interfacing with 8051:

The 8051 microcontroller outputs control signals to the motor driver (ULN2003/L293D), which amplifies the current required for the stepper motor coils. Port 2 of the 8051 is used to send control signals to the driver inputs.

#### 5) Step Sequence for 4-Step Operation:

- Step 1 → 0x09 (1001)
- Step 2 → 0x0C (1100)
- Step 3 → 0x06 (0110)
- Step 4 → 0x03 (0011)

To reverse the direction, the sequence is reversed.
